Contents

If one calculates the energy of a point charge using classical electromagnetism, the result is infinite, yet as far as we know, the electron is point charge. One can calculate the energy needed to assemble an electron due, essentially, to the interaction of the electron with its own field. A uniform charge distribution with the classical radius of an electron, we have an energy $m_e c^2$. Experiments have probed the electron's charge distribution and found that it is consistent with a point charge down to distances much smaller than the classical radius. Beyond classical calculations, the self energy of the electron calculated in the quantum theory of Dirac is still infinite but the divergences are less severe.

At this point we must take the unpleasant position (constant) infinite energy should just be subtracted when we consider the overall zero of energy (as we did for the field energy in the vacuum). Electrons exist and don't carry infinite amount of energy baggage so we just subtract off the infinite constant. Nevertheless, we will find that the electron's self energy may change when it is a bound state and we should account for this change in our energy level calculations. This calculation will also give us the opportunity to understand resonant behaviour in scattering.

We can calculate the lowest order self energy corrections represented by the two Feynman diagrams below.

In these, a photon is emitted then reabsorbed. As we now know, both of these amplitudes are in order e^2 . The first one comes from the A^2 term in which the number of photons changes by zero or two and the second comes from the $\vec{A} \cdot \vec{p}$ term in second order time dependent perturbation theory. A calculation of the first diagram will give the same result for a free electron and a bound electron, while the second diagram will give different results because the intermediate states are different if an electron is bound than they are if it is free. We will therefore compute the amplitude from the second diagram.

$$H_{\text{int}} = -\frac{e}{mc} \vec{A} \cdot \vec{p}$$

$$\vec{A} = \frac{1}{\sqrt{V}} \sum_{\vec{k}, \alpha} \sqrt{\frac{\hbar c^2}{2\omega}} \hat{\epsilon}^{(\alpha)} \left(a_{\vec{k}, \alpha} e^{i(\vec{k} \cdot \vec{x} - \omega t)} + a_{\vec{k}, \alpha}^\dagger e^{-i(\vec{k} \cdot \vec{x} - \omega t)} \right).$$

This contains a term causing absorption of a photon and another term causing emission. We separate the terms for absorption and emission and pull out the time dependence.

$$H_{\text{int}} = \sum_{\vec{k}, \alpha} \left(H_{\vec{k}, \alpha}^{\text{abs}} e^{-i\omega t} + H_{\vec{k}, \alpha}^{\text{emit}} e^{i\omega t} \right)$$

$$H_{\vec{k}, \alpha}^{\text{abs}} = -\sqrt{\frac{\hbar e^2}{2m^2 \omega V}} a_{\vec{k}, \alpha} e^{i\vec{k} \cdot \vec{x}} \vec{p} \cdot \hat{\epsilon}^{(\alpha)}$$

$$H_{\vec{k}, \alpha}^{\text{emit}} = -\sqrt{\frac{\hbar e^2}{2m^2 \omega V}} a_{\vec{k}, \alpha}^\dagger e^{i\vec{k} \cdot \vec{x}} \vec{p} \cdot \hat{\epsilon}^{(\alpha)}.$$

The initial and final state is the same $|n\rangle$, and second order perturbation theory will involve a sum over intermediate, and second order perturbation theory will involve a sum over intermediate atomic states, $|j\rangle$ and photon states. We will use the matrix elements of the interaction Hamiltonian between those states.

$$\mathbf{H}_{jn} = \langle j | \mathbf{H}_{k,\alpha}^{\text{emit}} | n \rangle .$$
